Aim: To implement Booth's algorithm using c-programming.

Objective -

- 1. To understand the working of Booths algorithm.
- 2. To understand how to implement Booth's algorithm using c-programming.

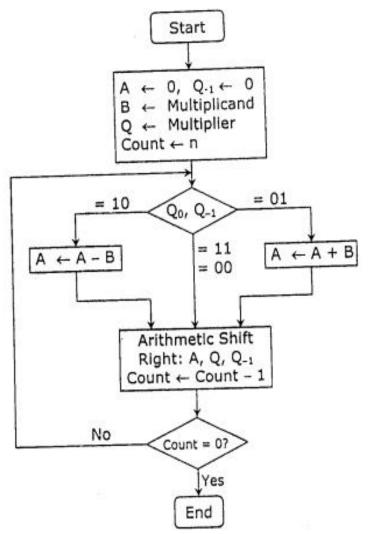

Theory:

Booth's algorithm is a multiplication algorithm that multiplies two signed binary numbers in 2's complement notation. Booth used desk calculators that were faster at shifting than adding and created the algorithm to increase their speed.

The algorithm works as per the following conditions:

- 1. If Qn and Q₋₁ are same i.e. 00 or 11 perform arithmetic shift by 1 bit.
- 2. If Qn $Q_{-1} = 10$ do A = A B and perform arithmetic shift by 1 bit.
- 3. If Qn $Q_{-1} = 01$ do A = A + B and perform arithmetic shift by 1 bit.

Steps	Α				Q				Q-1	Operation
	0	0	0	0	0	1	0	0	0	Initial
Step 1:	0	0	0	0	0	0	1	0	0	Shift right
Step 2 :	0	0	0	0	0	0	0	1	0	Shift right
Step 3:	1	0	1	1	0	0	0	1	0	A ← A – B
	1	1	0	1	1	0	0	0	1	Shift right
Step 4:	0	0	1	0	1	0	0	0	1	A ← A + B
	0	0	0	1	0	1	0	0	0	Shift right
Result	0	0	0	1 0	1 (0	=	+20

Conclusion -

Implementing Booth's algorithm in C programming offers an efficient method for multiplying binary numbers. This algorithm optimizes the process by minimizing the number of additions and subtractions required. By carefully managing the bit-wise operations, we can significantly reduce computational overhead. This not only enhances computational speed but also conserves resources, making it a valuable tool for various applications where binary multiplication is crucial, such as in computer architecture and digital signal processing.
